Point estimations

- Most machine learning students are used to "**point estimators**", i.e., $\arg \max_{\theta} (f_{\theta}(X))$
- ▶ In estimating parameters of a distribution: Maximum Likelihood Estimation (MLE), Maximum A Posterior (MAP),
- In situations where we cant solve $\arg\max_{\theta} (f_{\theta}(X))$ analytically, we resort to some iterative methods, for examples, Expectation-Maximisation (EM)

MLE Example

Normal distributed data

You believe data is Normal distributed:

Maximum Likelihood Estimation

which "normal" distribution parameter $\theta = (\mu, \sigma)$ is more likely?

$$\begin{aligned} \theta^{\mathsf{MLE}} &= \arg\max_{\theta} \left(\log[p(X|\theta)] \right) \\ &= \arg\max_{\theta} \left(\sum_{i=1}^{N} \log[\mathcal{N}(x_i; \mu, \sigma)] \right) \end{aligned}$$

► How to solve "argmax"? Well easy, take the deriviative and let it equal zero. Works in the Gaussian case.

MAP Example

Nhat if I have some prior knowledge of of μ , for example, $\mu \sim \mathcal{N}(\mu_0, \sigma_0)$. This type of estimation is called Maximum a Posterior (MAP):

$$\theta^{\mathsf{MAP}} = \arg\max_{\theta} \left(\log[p(X|\theta)p(\theta)] \right)$$

Say what you need is to find the mean, i.e.,

$$\mu^{\mathsf{MAP}} = \arg\max_{\mu} \left(\sum_{i=1}^{N} \log[\mathcal{N}(x_i|\mu,\sigma)\mathcal{N}(\mu;\mu_0,\sigma_0)] \right)$$

► How to solve "argmax"? Well easy, take the deriviative and let it equal zero. Works in the Gaussian case.

MAP Example Conti.

- ightharpoonup Same trick applies: take the derivative with respect of μ and let it equal zero
- ▶ If you write out the expression for Gaussian fully, you will get:

$$\mu^{MAP} = \frac{n\sigma_0^2}{n\sigma_0^2 + \sigma^2} \left(\frac{1}{n} \sum_{j=1}^n x_i \right) + \frac{\sigma^2}{n\sigma_0^2 + \sigma^2} \mu_0$$

▶ see what happens if $\sigma_0 \to \infty$

Expectation Maximization

- ▶ If lucky, can find arg $\max_{\theta} \log[p(X|\theta)p(\theta)]$, i.e., take the derivative and let it equal zero analytically
- In many cases, we have to use some numerical methods, such as Expectation-Maximization (EM) http://www-staff.it.uts.edu.au/ ydxu/stat/incremental.pdf
- ▶ Given an initial parameter θ^1 , we obtain a set of parameter estimate $\{\theta^1, \dots \theta^g, \theta^{g+1}, \dots\}$, such that:

$$\log[p(X|\theta^{g+1})p(\theta^{g+1})] \ge \log[p(X|\theta^g)p(\theta^g)]$$

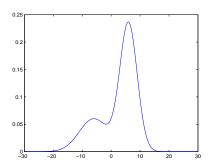

Two examples

- ► Gaussian Mixture model: $p(x|\theta) = \sum_{l=1}^{M} \mathcal{N} w_l(x; \mu_l, \sigma_l)$
- ► An example of my research: (Xu & Kemp, 2010 & 2013)
- both are solved using expectation maximization

The moral of the story

- Doesn't matter how sophisticated they are, these algorithms are point estimators, as they simply give you a "best" **single** θ .
- In many machine learning problems, you are actually interested in the posterior distribution $p(\theta|\text{Data}) \propto p(\text{data}|\theta)p(\theta)$
- ▶ Ok, let's look at an example:

A simple "almost real" posterior inference problem

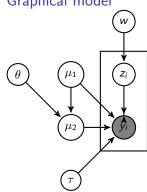

- ▶ A simple problem where data points $Y = \{y_1, ..., y_N\}$ are distributed from a bi-modal Gaussian Mixture Model
- ▶ The two gaussians have their means at μ_1 and μ_2 , separately by a distance θ
- **ightharpoonup** Both Gaussians have the identical precision au
- First Gaussian has a weight w_1 , and the second has w_2
- ▶ We also assume the latent variable $z_i \in \{1, 2\}$, indicating which Gaussian has generated y_i
- ▶ The Generative model and its Graphical model is shown in the next page

A simple "almost real" posterior inference problem

Generative model

$$egin{aligned} w &\sim \mathsf{Dir}(lpha,lpha) \ au &\sim \mathsf{Gamma}(a,b) \ heta &\sim \mathcal{N}(0,\sigma_{ heta}^2) \ au_1 &\sim \mathcal{N}(0,\sigma_{\lambda}^2) \ az_i | w &\sim \mathsf{Mult}(w) \ au_2 &\sim \mathbf{1}(\mu_1+\theta) \ y_i | \mu_{z_i}, au &\sim \mathcal{N}(\mu_{z_i},1/ au) \end{aligned}$$

Graphical model

- What you are hoping to get is of course $p(z_i, w, \mu_1, \mu_2, \tau, \theta | \{y_1, \dots, y_N\})$
- **Exercise** Write down the posterior densities for each of the variables, using appropriate conditional independence depicted in the Graphic model.

Any easy way out? To use black-box sampler

- What if I don't want to write my own sampling code?
- ▶ The good news is that you don't have to. You can simply use WINBUGS.
- http://www.mrc-bsu.cam.ac.uk/bugs/winbugs/contents.shtml
- ▶ Or, modern-day STAN: http://mc-stan.org
- ▶ To use **WINBUGS**, the previous example can be coded into:

```
inits in "eyes.in";
model eyes:
                                                 {for (i in 1:N){
const
                                                     y[i] \sim dnorm(mu[z[i]],tau);

T[i] \sim dcat(P[])
     N = 48:
var
                                                 sigma < -1/sqrt(tau);
                                                 tau \sim dgamma(0.01,0.01);
                                                theta.
                                                theta \sim dnorm(0,1.0E-6) I (0,);
    tau,
                                                 w[] \sim ddirch(alpha[]);
    sigma,
                                                alpha[1] < -1; alpha[2] < -1;}
     alpha[2];
data y in "eyes.dat";
```

Can I leave now?

No :)

- ➤ Can't just use WINBUGS or STAN for all models; They are black-box sampler.
- In many scenarios, you need to develop your own efficient sampling
- **>** . . .

Ok, let's start sampling!

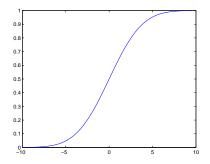

Any other methods for for posterior inference

Other methods also exist for posterior inference:

- Variational Bayes good starting point: chapter 10 of Bishop's textbook, and/or my notes
- ► Laplace approximation
- **.**..

Simplist method: inverse of CDF

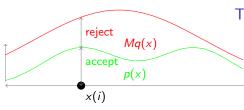

Simplist sampling method: sample the inverse of CDF!

$$u \sim U(0,1)$$
 $x = CDF^{-1}(u)$

Rejection Sampling

- ► Sampling is all about efficiency
- Rejection sampling can give you quite low acceptance ratio, should you choose a non-compatible q(.)

The algorithm

```
i = 0
while i \neq N
    x(i) \sim q(x) and u \sim U(0,1)
    if u < \frac{p(x(i))}{Mq(x(i))} then
        accept x(i)
         i = i + 1
    else
         reject x(i)
    end
end
```

Adaptive Rejection Sampling

Sometimes, rejection sampling can be made more efficient. One example is when p(x) is log-concave. For example, in Dirichlet Process, the concentration factor α has probability:

$$p(\alpha|k,n) \propto \frac{\alpha^{k-3/2} \exp(-1/(2\alpha))\Gamma(\alpha)}{\Gamma(n+\alpha)}$$

where $p(\cdot)$ is log-concave in terms of $\log(\alpha)$

Homework prove the above is in fact log-concave in terms of $log(\alpha)$

ARS steps

- Let $\{x_i, \dots, x_k\}$ be the k starting points.
- Calculate $u_k(x)$, the piece-wise linear upper bound formed from the tangents to h(x) at each point x_i
- $> s_k(x) = \frac{\exp(u_k(x))}{\int \exp(u_k(x'))dx'}$
- $z_j = h(x_{j+1}) h(x_j) x_{j+1}h'(x_{j+1}) + x_jh'(x_j)$ $h'(x_j) - h'(x_{j+1})$
- Piece-wise upper bound: $u_k(x) = h(x_j) + (x - x_j)h'(x_j)$ for $x \in [z_{j1}, z_j]$ and j = 1, ..., k

The Sampling steps

- Sample $x^* \sim s_k(x)$ and $u^* \sim U(0,1)$.
- ▶ If $u^* \le \exp\{h(x^*)u_k(x^*)\}$ then accept x^* , otherwise reject x^* .
- Include x^* in the list, so it has K+1 elements, and rearrange in ascending order and reconstruct functions $u_{k+1}(x), s_{k+1}(x)$

ARS demos

- Watch demo of sampling a Gaussian distribution (no need to use ARS, but ok for demo)
- ► Homework Find some other log-concave distributions
- What happens to distribution in which it is NOT log-concave?
- ▶ It may be break up into piece-wise, concave/convex: Further readings: Grr, Dilan, and Yee Whye Teh. "Concave-convex adaptive rejection sampling." Journal of Computational and Graphical Statistics 20.3 (2011): 670-691

Further improve ARS efficiency

- ► The algorithm you saw in the MATLAB demo require the computation of a new envelope each time.
- ▶ Is it really necessary after the envelop becomes "pretty good"?
- ► **Exercise** What is the most computational step in the envelope computation?
- **Exercise** Can you accept samples without recompute the envelope?

Importance Sampling

Say, for example, the aim for this task is to compute the integral:

$$E_{p(z)}[f(z)] = \int f(z)p(z)dz$$

$$= \int \underbrace{f(z)\frac{p(z)}{q(z)}}_{\text{new}\tilde{f}(z)}q(z)dz$$

$$\approx \frac{1}{N}\sum_{n=1}^{N}f(z^{i})\frac{p(z^{i})}{q(z^{i})}$$

 $ilde{p}$ is the un-normalized pdf, i.e., $p(z)=rac{ ilde{p}}{Z}$
